

Top Indian Market Trading/Investment Strategies (Quantified Backtests)

We have identified several well-backed strategies for Indian equities and index options (NIFTY and BANKNIFTY), suitable for medium-high risk traders. Each combines clear rules with demonstrable backtested performance. Below is a summary table and detailed descriptions of the strategies, including their market, type (intraday vs positional), historical returns/drawdown, data/tools, and key signals. Wherever possible, we cite backtest results and reference code or notebooks.

Strategy	Market	Type	Backtested Performance	Tools/Data	Signals / Rules
1. BankNIFTY Opening-Range Breakout	Bank Nifty futures	Intraday	~352% total (2015–2023), ~39%/yr (no compounding); Max DD: ~48% 1	Python (pandas, backtesting libs); NSE/BSE historical futures data	Bullish: Close above high of first 15-min candle (9:15–9:30 AM); Bearish: Close below low. Exit trades at 3:15 PM or on fixed SL at opposite end of first candle.
2. BankNIFTY Rolling Short Straddle	Bank Nifty weekly options	Intraday (expiry-day)	Avg ₹1,032 profit/day (2017–2022) 2 (roughly ~20–30% annualized); DD not given in source.	Python (pandas, numpy); NSE option-chain data (e.g. NSEpy or Zerodha API)	Sell ATM Call & Put at 9:20 AM on expiry days. Set 200-pt SL on each leg. Allow up to 3 re-entries/day after a stop trigger. Fixed profit/trailing (per backtest rules). (Details: UpsurgeClub “Rolling Straddle” 2 .)

Strategy	Market	Type	Backtested Performance	Tools/Data	Signals / Rules
3. BankNIFTY ATM Intraday Straddle	Bank Nifty index options	Intraday	~260% total return in 2.3 years (Jan 2019– Apr 2021) ³ ; ~ Max DD : ~15% (≈ ₹39k on ₹1L capital)	Python (pandas); NSE option- chain data	Sell 1 lot ATM Call and ATM Put at ~9:25 AM. Use a 30% stop-loss and 60% profit target on each leg; exit at 3:15 PM if neither hit. (Example: Reddit “9:25 Straddle” backtest ³ .)
4. Dual Momentum (Nifty/Gold)	NIFTYBEES & GOLDBEES ETFs	Positional (swing)	CAGR ~16.1% (2010–2024), total +1221.5%; Max DD : – 23.51% ⁴ . Outperforms buy-and-hold (NiftyB DD –55%) ⁴ .	Python (pandas); Yahoo Finance or Google (ETFs data)	Every quarter compare last 3- month total returns of Nifty index (NIFTYBEES) vs Gold (GOLDBEES) ETFs. Invest fully in the higher-momentum ETF. (Switch quarterly.) This “dual momentum” rotation significantly lowered drawdowns while boosting returns ⁴ .
5. NIFTY 50/200-Day SMA (Golden Cross)	NIFTY index	Positional (trend- following)	Avg +24.4% one- year gain following each 50-day/200-day SMA golden cross (2019– 2025) ⁵ . (Historic study: Nifty hit new highs after each golden cross.)	Python (pandas, TA- Lib) or even Excel; Yahoo/ NSE data	Entry : 50-day SMA crosses above 200- day SMA on daily Nifty. This “golden cross” historically has heralded large uptrends ⁵ . Traders go long Nifty (e.g. Nifty futures or index ETFs) on this signal. (Exit could be on the reverse 50×200 “death cross”.)

Strategy	Market	Type	Backtested Performance	Tools/Data	Signals / Rules
6. 52-Week High Breakout (Stocks)	Nifty 50 component stocks	Swing (weeks–months)	Among stocks breaking 52-week highs, 68% of such breakouts generated ~42% avg simple return (5-year window) ⁶ .	Python (pandas, TA-Lib); price data via Yahoo or NSEPY	Entry: Identify Nifty 50 stocks making new 52-week highs. Require confirmation (e.g. price above 10-day SMA, and 10>20>50>100-day SMA alignment as filter). Enter long on breakout closes; use a trailing stop (e.g. 20-day SMA) or fixed stop. (Stackademic backtest suggests many stocks continued up significantly ⁶ .)
7. Multi-Month Momentum (Nifty200)	Nifty 200 stocks	Positional (rotational)	Example: “Rate-of-Change (ROC) 6m,12m; rebalance 2-wk” strategy gave CAGR ~23.0%, Max DD ~-34.7% over 10 years ⁷ . (Shorter lookbacks gave even higher ~40%/yr on 5y ⁸ .)	Python (pandas); use Nifty200 constituents from Yahoo/ NSE	Rank Nifty200 stocks by multi-month returns (e.g. 6- and 12-month ROC). Invest in top decile and rebalance periodically (e.g. biweekly or monthly). This momentum approach produced strong gains (albeit with ~30–35% drawdowns ⁷). A 200-day MA filter (only hold positions when overall market is above 200DMA) can reduce risk.

Summary of Tools & Data: All of the above can be implemented with open-source Python libraries. Typical libraries include *pandas/numpy* for data manipulation, *TA-Lib* or *pandas-ta* for indicators, and backtesting

frameworks (e.g. Backtrader, zipline, backtesting.py). Data can be obtained via *Yahoo Finance* (using `yfinance` or `pandas_datareader`), the *NSEPy* library for Indian market data, or broker APIs. Options data (Nifty/BankNifty option chains) may be sourced from NSE APIs or historical data repositories.

Code Examples: Sample code and backtests are available online. For example, a GitHub repository provides a full Python backtest of a BankNifty short-straddle strategy ⁹. The Stackademic post (strategy 6) includes Python code for the 52-week high breakout. In practice, one would write Python scripts or Jupyter notebooks to download price data, generate signals per the above rules, simulate trades, and compute metrics (CAGR, drawdown).

Key Observations:

- *Breakout strategies* (like ORB) exploit intraday volatility and have delivered very high gross returns, but with large drawdowns (~40–50%) ¹ unless position sizes or capital buffers are adjusted.
- *Option-selling* (short straddles/strangles) can yield steady income, especially on BankNifty due to high premiums. For example, the “rolling straddle” tweak (200-pt stops, limited trades, expiry days only) averaged ~₹1,000/day profit ². A single-entry ATM straddle with tight SL/TP achieved ~260% in ~2 years ³.
- Caution:** such strategies can suffer huge losses if a big gap move hits the stop (as noted in a Moneycontrol review of the 9:20 straddle ^{10 11}).
- *Momentum/rotational strategies* smooth out risk. For instance, rotating between Nifty and Gold (dual momentum) drastically cut drawdowns (max -23.5%) while yielding ~16% CAGR ⁴. Similarly, ranking stocks by multi-month momentum produced 20–40% annual returns ⁸, albeit with ~30% drawdowns ⁷.
- *Trend-following filters* (e.g. 50/200 DMA) have historically reduced risk. In India, a 50×200 SMA “golden cross” on Nifty has often preceded strong rallies (averaging +24.4% gain) ⁵.

Each strategy requires adequate capital, risk management and realistic cost assumptions. For example, slippages/commissions can erode short-term edge (as seen with the 5-EMA scalping strategy, which was profitable pre-costs but not net ¹²). Retail traders can implement these methods using free data/APIs and backtesting in Python. The above strategies are supported by published backtests ^{1 4 3 5 2 6 7} and represent a mix of intraday and longer-term approaches with demonstrated high returns.

Sources: Backtest performance and strategy details are drawn from publications and code (e.g. Sai Mohan Reddy’s BankNifty analyses ¹, a Reddit backtest ³, a TradingQnA post ⁴, Business Standard markets news ⁵, a Stackademic strategy blog ⁶, a MomentumLab study ⁷, and others). Python backtest examples (e.g. on GitHub ⁹) illustrate implementation. Each strategy description above cites these connected sources.
